1 Quadratic and linear convergence of newton Raphson method.

1.1 Description - Problem 1

Consider the function 1 interval [0,3]

$$f(x) = 12 - 26x + 20x^2 - 7x^3 - 12e^{x-2} + 12xe^{x-2}$$
 (1)

- 1. Plot the function to get some ideas of the zeroes and choose suitable initial guesses.
- 2. Apply the Newton-Raphson method to find both zeroes of the function f(x).
- 3. For each root print out:
 - The sequence of iterates.
 - The absolute error $|E_i|$.
 - The absolute relative error ratio $\frac{|E_{i+1}|}{|E_i|}$ and $\frac{|E_{i+1}|}{(|E_i|)^2}$ that converges to a nonzero limit

Each of those print out can be found in the Results part in 1.4 on page 5.

1.2 Description - Problem 2

- 1. Determine for which root the convergence is quadratic, and also compute the asymptotic error constant A.
- 2. If for one of the roots the method does not show quadratic convergence, explain why it doesn't, i.e. why the theorem on quadratic convergence isn't applicable.
- 3. Does it obey linear convergence? If yes, why?

1.3 Solution

```
1 %show graph
2 plt func
4 f = @(x) 12 - 26.*x + 20.*x^2 - 7.*x^3 - 12.*exp(x-2) + 14 .*x.*exp(x-2)
5 % Settings
approx1 = 0.2
                % Approximation for f(x) = 0 poor guess to get many rep.
7 \text{ approx}2 = 1.9
8 \text{ toll} = 1e-9
9 \text{ tol2} = 1e-9
_{10} rep = 20
11 % Derivitive.
 df = @(x) -21.*x.^2+40.*x+14.*x.*exp(x-2)+2.*exp(x-2)-26; 
13 ddf = @(x) 14.*x.*exp(x-2)-42.*x + 16.*exp(x-2)+40;
14 % Find error with nownon.
17 % Write data to disk.
t writer(xn1, xn2);

Table 3: Table for root 2

1.5 Analysis of results

1.5.1 Problem 1

- 1. Fig 1 show the plot of f(x) and we chose $x_1 = 0.2$ and $x_2 = 1.9$ as our initial guesses to approximate the roots for the function. To get a considerable amount of iterations we had to make "bad guesses", otherwise it would even for low tolerances yield only 2-3 iterations before finding an approximation of the root which was to little data to analyse.
- 2. Applying the Newton-Raphson method yields an solution for $x_1 = 0.857142857089488$ after 7 iterations and solution for $x_2 = 1.999515482374499$ after 14 iterations with a tolerance of $T_{tol} = 10^{-9}$.

3. The data is shown in the tables in 1.4.3.

1.5.2 Problem 2

- 1. From table 1 we see that the root x=2 seems to converge when R=1 very steadily. For $x_1\approx 0.857$ however with so few iterations it is hard to see any convergence, but we conclude that for R=2 it seems to converge to a value. Our conclusion is that $x_2=2$ has a linear convergence and $x_1\approx 0.857$ has a quadratic convergence. Using the formula $M=\frac{f''(x)2}{f'(x)}$ we get M=2.413850894567771 which correlates with the value x_1 seems to converge to. This is also the asymptotic error constant. For x=2, A=0.666528351347989 and for $x_1=0.857$, A=2.4XXX.
- 2. For the root x = 2 the method doesn't show quadratic convergence, this is because x = 2 is a root but also an extreme point for the function so the derivative at this point is zero which yields division by zero using the formula to compute M.
- 3. The formula which calculates the asymptotic error constant $\frac{E(i+1)}{E(i)^R} = A$ rewritten to compute the next absolute error is $E(i+1) = A*E(i)^R$. For R=1 this is a linear equation, for R=2 a quadratic equation and for R=3 a cubic equation and so on. For our case the root x=2 converges when R=1 and therefore follows linear convergence.
